# CHAPTER 1

---

## Introduction

---

Introductory text.

# CHAPTER 2

---

## Changelog

---

### 2.1 v0.1.0 (June 15, 2017)

- Initial project is up and running.

# CHAPTER 3

---

## Functions

---

We have a simple function that adds two numbers

```
python_template.add(x, y)  
The sum of two numbers.
```

### Parameters

- **x** ((*int, float*)) – The first number to be added.
- **y** ((*int, float*)) – The second number to be added.

**Returns** **ret** – The sum of the inputs a and b

**Return type** (*int, float*)

### Notes

Python will often convert the types of the input values. For example if the input of x and y are integers the result will be in an integer. However if the input is a integer and a float a float will be returned.

### Examples

Adding two integers together:

```
>>> add(5, 3)  
8
```

An example of mixed input type:

```
>>> add(5.0, 3)  
8.0
```

We also have the popular Levenshtein distance estimator

`python_template.text.levenshtein(seq1, seq2)`

Function to compute the Levenshtein distance between two strings. Reference: [https://en.wikipedia.org/wiki/Levenshtein\\_distance](https://en.wikipedia.org/wiki/Levenshtein_distance)

#### Parameters

- `seq1 (str)` – The first string to compare
- `seq2 (str)` – The second string to compare

**Returns** `distance` – The Levenshtein distance between two strings

**Return type** int

#### Notes

The Levenshtein distance between two words is the minimum number of single-character edits required to change one word into the other. This is often very useful for finding approximate string matches. For example throwing an error with suggestions due to a keyword mismatch.

#### Examples

Find the distance between kitten and sitting:

```
>>> levenshtein("kitten", "sitting")  
3
```

# CHAPTER 4

---

## PyTest Guide

---

This is a quick guide for PyTest. See [PyTest](#).

# CHAPTER 5

---

## Indices and tables

---

- genindex
- modindex
- search

---

## Index
